Abstract

This paper announces the discovery of the use of neural nets almost 4,000 years before their use in the modern era. Newly discovered tablets preserve a perceptron used for calculating the numbers on Plimpton 322, the most important object in the history of mathematics. The native programming language used by the ancient Babylonian "cuneogrammers" uses sexagesimal numbering leading to some "weirdness".

test

1 Introduction

(Robson, 2002)

2 Discovery

Museum of the Sealand

Unfortunately, the hardware required to execute these programs (i.e. a living Babylonian mathematician) has not been adequately preserved, but we have managed to write a Python library which emulates it.¹

3 Description of the Language

Programs in  follow a tabular structure with three main sections: (i) a header, denoted by DUB  ("tablet"), (ii) a sequence of instructions, and (iii) a colophon detailing the tablet's authorship. Each instruction spans four columns, which we have taken to calling the *arguments*, *opcode*, *destination*, and *line number*. These columns are usually tab-separated, though in a few documents they are TAB-separated (using the cuneiform sign TAB ). Instructions are grouped into blocks by means of horizontal lines.

Arguments An instruction's arguments may be numbers, register addresses, or a combination of the two. Numbers are encoded following standard Babylonian conventions (?), with  denoting the radix point which separates the integer part from a following fraction. There is an explicit representation for zero (), making these tablets some of the earliest unambiguous examples of the mathematical concept of zero.

A register address is denoted by the phrase NID₂.KAS₇ *n*-KAM *n* ("thing.account *n*-th", "the item in the *n*-th place"), where *n* is any number.  expressions can be nested to perform a kind of pointer dereferencing: for example, if  (register 1) contains the value  (3), and  (register 3) contains the value  (7), then  will evaluate to 7 (the value in the register pointed to by ).

If an instruction has multiple arguments, these must be delimited by a wide space (distinct from the short space used to separate groups of digits within a number), or by one of the phrases *a-na*  "to" or *i-na*  "from". By convention, the choice of delimiter depends on the instruction's opcode (see below), with multiplication operations preferring space delimiters, addition preferring , and subtraction preferring . There is no mechanism to enforce these conventions, but we recommend following them because  is hard enough to read at the best of times.

Destination In most cases, the destination column of an instruction will be a register address where the output is to be stored, e.g. . Some control-flow instructions (see below) instead expect the destination to be a line number.  SUD ("distant, remote") can be used as a null destination, for statements which produce no output.

to higher digits and thus begin to overwrite one another. This limitation may explain why AI never made waves in Babylonian society, as their models were all too small to be truly revolutionary.

4 Description of the Texts

- add graph plotting perceptron output vs true trigonometric ratios from Plimpton

5 Implications

This completely rewrites the history of modern computing...

Other ancient corpora which have resisted decipherment, and which boast a similar numeric component, may represent additional examples of ancient programming traditions.

- compare the table of params at the end of the file to tables of astronomical parameters from genuine tablets
